INTRODUCTION: People have paid much attention to optical properties in parity-time ($\mathcal{PT}$) symmetric system during recent years both theoretically and experimentally [1–6]. Bender et al. found that the non-Hermitian Hamiltonian with $\mathcal{PT}$ symmetry can exhibit entirely real spectrum [7]. In optics, $\mathcal{PT}$ symmetric potentials can be also constructed by a complex gain/loss refractive-index distribution into the waveguide, which make the refractive index distribution is $\mathcal{PT}$ symmetry [1–3]. Many unusual features stemming from $\mathcal{PT}$ symmetry have been found, such as power oscillation [8], absorption enhanced transmission [6], nonlinear switching structure [9], and unidirectional invisibility [10].

But the properties of $\mathcal{PT}$ symmetry mentioned above are mostly discussed by numerical simulations and experimental results. In order to get a good understanding of the properties of $\mathcal{PT}$ symmetry solitons, it is essential to present an analytic solution, even an approximate one. Musslimani et al. have present closed form solutions to a certain class of nonlinear Schrödinger equations involving $\mathcal{PT}$ symmetry potential [11]. R.EI-Ganainy et al. have developed a formalism for coupled optical parity-time symmetric systems by Lagranian principles [1]. It would be very desirable to obtain approximate analytical results for the general $\mathcal{PT}$ symmetry Schrödinger equations. For the nonlinear Schrödinger equations, the approximate solutions can provide a better physical understanding of the interplay between $\mathcal{PT}$ symmetry potential and nonlinear effects in connection with solitons propagation. The variational method has been widely applied to obtain approximated solutions for problems concerning beam propagation within the framework of the NLSE [13]. Motivated by the previous works in which it was studied the dissipative solitons solutions by the variational approach [14, 15]. In this paper, we will employ a variational approach based on the dissipative system to deal with the Schrödinger equation with $\mathcal{PT}$ symmetric Gaussian complex potential, and some unusual properties in $\mathcal{PT}$ system can be analyzed by this method. Following numerical simulations, the analytical results are in good agreement with the numerical results.

gain) in the medium. Equation (3) can be applicable to the general dissipative system. At the center of the $\mathcal{PT}$ system, we have

$$\left(\phi^2 \partial_x \phi\right)|_{x=0} = \int_0^\infty W(x) \phi^2 dx = -\int_{-\infty}^0 W(x) \phi^2 dx.$$  \hspace{1cm} (4)

That means the energy-flow at the center must equal to the total loss (or gain) at each side. As a result, the intensity at the center can not be zero for any stable solution and the dark solitons can not exist in any $\mathcal{PT}$ system.

**VARIATIONAL METHOD:**

According to the literatures [14, 15], the Lagrangian for Eq. (1) is the sum of two terms, a conservative one $L_C$ and a non-conservative one $L_{NC}$, where

$$L_C = \frac{i}{2} \left( U \partial_z U^* - U^* \partial_z U \right) + |\partial_z U|^2 - V |U|^2 - \sigma \frac{1}{2} |U|^4. \hspace{1cm} (5)$$

The $\mathcal{PT}$ symmetric gaussian complex potentials are used here as $V(x) = V_0 \exp(-x^2)$ and $W(x) = W_0 x \exp(-x^2)$, where $V_0$ and $W_0$ represent the depth of the real and the imaginary parts of $\mathcal{PT}$ potentials respectively [16]. We suppose the trial function as,

$$U = a(z) \exp\left(-\frac{x^2}{2w(z)^2} + i\theta_0(z) \text{erf}\left[\frac{x}{w_1(z)}\right]\right) \times \exp[iC(z)x^2 + i\Phi(z)], \hspace{1cm} (6)$$

where $a(z)$, $w(z)$, $C(z)$, and $\Phi(z)$ stand for the amplitude, width, chirp and the phase of the beam, $\theta_0(z)$, and $w_1(z)$ stand for the amplitude and the width of wavefront lean $\theta$. By substituting the trial solution into Eq.(5) and the averaged conservative Lagrangian can be obtained,

$$< L_C > = \int_{-\infty}^{+\infty} L_C dx = \frac{\sqrt{\pi a^2 w^3}}{2} \frac{dC}{dz} + \frac{\sqrt{\pi a^2 w^3}}{2} \frac{d\Phi}{dz} + \frac{\sqrt{\pi a^2 w^3}}{2} \left[ \frac{(w_1)^2}{w^2} \right]^{1/2}$$

$$+ \frac{4a^2 \theta_0^2 w}{\sqrt{\pi w_1^2 w^2 + w^4}} + 2\sqrt{\pi} C^2 a^2 w^3$$

$$- \frac{\sqrt{\pi} \theta_0^2 a^2 w^3}{\sqrt{w^2 + 1}} - \frac{2\sqrt{\pi} a^2 w^3}{4}. \hspace{1cm} (7)$$

The Euler-Lagrange equations for parameter $\eta$ is

$$\frac{d}{dz} \left( \frac{\partial < L_C >}{\partial \eta} \right) - \frac{\partial < L_C >}{\partial \eta} = 2Re \left\{ \int_{-\infty}^{+\infty} \frac{Q}{\partial \eta} dx \right\} \hspace{1cm} (8)$$

in which $Q = -i W(x) U$ is the dissipative term in Eq. (1). Following the process [14, 15], substituting $\eta$ with $a$, $w$, $w_1$, $\theta_0$, $C$ and $\Phi$ into the Eq. (8), we arrive at the relations between the parameters,

$$w_1 \equiv 1, \hspace{1cm} \left\{ \begin{array}{l}
\frac{d(\sqrt{\pi} a^2 w)}{dz} = \frac{dP}{dz} = 0, \\
\end{array} \right. \hspace{1cm} (9)$$

$$\theta_0 = \frac{\sqrt{\pi} W_0 a^2}{4(w^2 + 1)}, \hspace{1cm} (10)$$

Equations (9) is a trial result which means the power of a stationary modes is unchanged during propagation. From Eqs.(10) and (11), we find that the shape of the phase function $\theta$ is independent of the beam width. Numerical simulations show that even for unstable solution, the shape of the phase function is very similar to the error function, and its amplitude ($\theta_0$) is mainly determined by $W_0$. We also find that these properties are identical to the multimode solitons and other $\mathcal{PT}$ systems such as Scarff II potential.

Introducing $P_0 = \sqrt{\pi} a^2 w$, we arrive at the evolution equations,

$$\frac{dw}{dz} = 4wC, \hspace{1cm} (12)$$

$$\frac{dC}{dz} = \mu(w) - 4C^2 - \frac{\sigma P_0}{2\sqrt{2\pi} w^3}, \hspace{1cm} (13)$$

$$\mu(w) = \frac{1}{w^4} - \frac{V_0}{(w^2 + 1)^{3/2}} + \frac{W_0^2 w^4}{2(w^2 + 1)(2w^2 + 1)^{3/2}}, \hspace{1cm} (14)$$

$$b = \frac{w^2 + 1}{2w^4} - \frac{3w^2 - 1}{2} \mu(w) + \frac{V_0}{2(w^2 + 1)^{3/2}} + \frac{\sigma}{4\sqrt{2\pi}} P_0. \hspace{1cm} (15)$$

**LINEAR MODES:** For the case of stable solution, the derivatives of beam width and curvature in the evolution equations are vanished. In linear propagation, i.e. $\sigma = 0$, we can get $C = 0$, $\mu(w) = 0$,

$$b = \frac{w^2 + 1}{2w^4} + \frac{V_0}{2(w^2 + 1)^{3/2}}. \hspace{1cm} (16)$$

From Eqs. (16), for a large value of $V_0$, we have a maximum value of $W_0C$, which can be regarded as the $\mathcal{PT}$-breaking point. For a small value of $V_0$, there doesn’t exist a maximum value of $W_0C$, however, when $W_0 = 2^{5/4}\sqrt{V_0}$, $b \rightarrow 0$, and $W_0$ can be regarded as the $\mathcal{PT}$-breaking point. Figures (1)(a) and (b) shows the relation to the eigenvalues with $W_0$ for different $V_0$ in numerical and variational method. We can see that for a large $V_0(V_0=10)$, the $W_0C$ obtained by the variational method is in good agreement with the $\mathcal{PT}$-breaking point in the numerical method, and for a small $V_0 (V_0 = 2)$, the $W_0$ is close to the $\mathcal{PT}$-breaking point. The $\mathcal{PT}$-breaking point with different $V_0$ in numerical method and the relation of the $W_0C$ or the $W_0'$ with $V_0$ in analysis are shown in the fig. (1)(d). One can see that the $W_0C$ or the $W_0'$ is in good agreement with the $\mathcal{PT}$-breaking point. Figure(1)(c) shows that the amplitude and the nontrivial phase of the eigenfunction are in good agreement with the numerical results too.

**SOLITONS:** For the nonlinear propagation, i.e. $\sigma = \pm 1$, we can get $C = 0$ and $\sigma P_0 = 2\sqrt{2\pi} w^3 \mu(w)$ for the...
PT solitons. For a given value of \( V_0 \) and \( W_0 \), the \( PT \) solitons obey

\[
b = \frac{w^2 + 1}{2w^4} + \frac{2w^2 - 1}{2} \mu(w) + \frac{V_0}{2(w^2 + 1)^{3/2}},
\]

\[
P_0 = 2\sigma \sqrt{2\pi} w^3 \mu(w).
\]

Without losing of generality, we take \( V_0 = 10 \) and \( W_0 = 5 \) in this subsection.

Figures (2) (a) and (b) are the relations between the power and the beam width of solitons with the propagation constants, respectively. The critical propagation constant \( b_c \) at zero power is the eigenvalue for the linear mode. When propagation constant \( b > b_c \), it is corresponding to the solitons in the self-focusing nonlinear media, otherwise it represents the solitons in the self-defocusing media. We can see that in the self-defocusing media, the power of the bright solitons decreases with increasing of the propagation constants, however, it is contrary to the bright solitons in the self-focusing media. However, the beam width decreases with increasing of the propagation constants in the whole region. The amplitude and the nontrivial phase of the solitons in numerical method and variational approach are shown in Figs. (2)(c) and (d), which are corresponding to the cases marked as circle symbols in Figs. 2(a) and (b). One can see that the analytical results are in agreement with the numerical results for both self-focusing and self-defocusing cases.

Stability of the solitons: From the evolution equations, Eq. (18), we define

\[
F = \frac{dw}{dz} = 4wC,
\]

\[
G = \frac{dC}{dz} = \mu(w) - 4C^2 - \frac{\sigma P_0}{2\sqrt{2\pi}w^3}.
\]

The equation associated with the the Jacoby determinant corresponding to the stability criterion is [14]

\[
\lambda^2 + 4C\lambda - 32C^2 - 4w \frac{d\mu(w)}{dw} - \frac{6\sigma P_0}{\sqrt{2\pi}w^3} = 0
\]

When \( Re(\lambda) = 0 \), or \( \lambda^2 < 0 \), solitons is stable. Substituting \( C = 0 \) and \( \sigma P_0 = 2\sqrt{2\pi}w^3 \mu(w) \) to Eq. (19), one has

\[
\lambda^2 = 4w \frac{d\mu(w)}{dw} + 12\mu(w) < 0.
\]

CONCLUSION: In conclusion, we have analyzed the properties of the beam in PT symmetric Gaussian complex potentials by the variation method. According to the analysis, the transverse power-flow density is associated with the wavefront lean \( \theta \) of the beam. For the linear case, the PT-breaking points are obtained by the variational approach, and the eigenvalue obtained by the variational approach are in agreement with the ones by the numerical method. For the nonlinear case, there exists a
the critical propagation constant for bright soliton existing in the self-focusing and self-defocusing media. The relations between the power of solitons with the propagation constants and the beam width are gotten analytically and confirmed by numerical simulations. The amplitude and the nontrivial phase of the solitons in both the self-focusing and self-defocusing media are agreement with the numerical results.
